Abstract. Signed systems were introduced as a general, syntax-independent framework for paraconsistent reasoning, that is, non-trivialised reasoning from inconsistent information. In this paper, we show how the family of corresponding paraconsistent consequence relations can be axiomatised by means of quantified Boolean formulas. This approach has several benefits. First, it furnishes an axiomatic specification of paraconsistent reasoning within the framework of signed systems. Second, this axiomatisation allows us to identify upper bounds for the complexity of the different signed consequence relations. We strengthen these upper bounds by providing strict complexity results for the considered reasoning tasks. Finally, we obtain an implementation of different forms of paraconsistent reasoning by appeal to the existing system QUIP.

1 Introduction

In view of today's rapidly growing amount and distribution of information, it is inevitable to encounter inconsistent information. This is why methods for reasoning from inconsistent data are becoming increasingly important. Unfortunately, there is no consensus on which information should be derivable in the presence of a contradiction. Nonetheless, there is a broad class of consistency-based approaches that reconstitute information from inconsistent data by appeal to the notion of consistency. Our overall goal is to provide a uniform basis for these approaches that makes them more transparent and easier to compare. To this end, we take advantage of the framework of quantified Boolean formulas (QBFs). To be more precise, we concentrate here on axiomatising the class of so-called *signed systems* [2] for paraconsistent reasoning; a second paper will deal with maximal-consistent sets and related approaches (cf. [4,5]).

[★] Originally published in proc. PCL 2002, a FLoC workshop; eds. Hendrik Decker, Dina Goldin, Jørgen Villadsen, Toshiharu Waragai (<http://floc02.diku.dk/PCL/>).

^{★★} The work was partially supported by the Austrian Science Foundation under grant P15068.

Our general methodology offers several benefits: First, we obtain uniform axiomatisations of rather different approaches. Second, once such an axiomatisation is available, existing QBF solvers can be used for implementation in a uniform setting. The availability of efficient QBF solvers, like the systems described in [3,12,11,15], makes such a rapid prototyping approach practicably applicable. Third, these axiomatisations provide a direct access to the complexity of the original approach. Finally, we remark that this approach allows us, in some sense, to express paraconsistent reasoning in (higher order) classical propositional logic and so to harness classical reasoning mechanisms from (a conservative extension of) propositional logic.

Our elaboration of paraconsistent reasoning is part of an encompassing research program, analysing a large spectrum of reasoning mechanisms in Artificial Intelligence, among them nonmonotonic reasoning [8], (nonmonotonic) modal logics [10], logic programming [7,17], abductive reasoning [9], and belief revision [6].

In order to keep our paper self-contained, we must carefully introduce the respective techniques. Given the current space limitations, we have thus decided to reduce the motivation and rather concentrate on a thorough formal elaboration. This brings us to the following outline: Section 2 lays down the formal foundations of our work, introducing QBFs and Default Logic. Section 3 is devoted to signed systems as introduced in [2]. Apart from reviewing the basic framework, we provide new unifying characterisations that pave the way for the respective encodings in QBFs, which are the subject of Section 4. This section comprises thus our major contribution: a family of basic QBF axiomatisations that can be assembled in different ways in order to accommodate the variety of paraconsistent inference relations within the framework of signed systems. We further elaborate upon these axiomatisations in Section 5 for analysing the complexity of the respective reasoning tasks. Finally, our axiomatisations are also of great practical value since they allow for a direct implementation in terms of existing QBF-solvers. Such an implementation is described in Section 6, by appeal to the system QUIP [8,7,9].

2 Foundations

2.1 Preliminary Notation

We deal with propositional languages and use the logical symbols $\top$, $\perp$, $\neg$, $\vee$, $\wedge$, $\rightarrow$, and $\equiv$ to construct formulas in the standard way. We write $\mathcal{L}_\Sigma$ to denote a language over an alphabet Σ of *propositional variables* or *atoms*. Formulas are denoted by Greek lower-case letters (possibly with subscripts). Finite sets $T = \{\phi_1, \dots, \phi_n\}$ of formulas are usually identified with the conjunction $\bigwedge_{i=1}^n \phi_i$ of its elements. The set of all atoms occurring in a formula ϕ is denoted by $\text{var}(\phi)$. Similarly, for a set S of formulas, $\text{var}(S) = \bigcup_{\phi \in S} \text{var}(\phi)$. The derivability operator, $\vdash$, is defined in the usual way. The *deductive closure* of a set $S \subseteq \mathcal{L}_\Sigma$ of formulas is given by $\text{Cn}_\Sigma(S) = \{\phi \in \mathcal{L}_\Sigma \mid S \vdash \phi\}$. We say that S is *deductively closed* iff $S = \text{Cn}_\Sigma(S)$. Furthermore, S is *consistent* iff $\perp \notin \text{Cn}_\Sigma(S)$. If the

language is clear from the context, we usually drop the index “ Σ ” from $Cn_\Sigma(\cdot)$ and simply write $Cn(\cdot)$ for the deductive closure operator.

For formulas φ , ϕ , and ψ , we define *positive* and *negative occurrences* as follows:

- the occurrence of φ in φ is positive,
- if φ occurs positively (negatively) in ϕ , then the corresponding occurrence of φ in $\neg\phi$ and $\phi \rightarrow \psi$ is negative (positive),
- if φ occurs positively (negatively) in ϕ , then the corresponding occurrence of φ in $\phi \vee \psi$, $\phi \wedge \psi$, and $\psi \rightarrow \phi$ is positive (negative).

Given an alphabet Σ , we define a disjoint alphabet $\Sigma^\pm$ as $\Sigma^\pm = \{p^+, p^- \mid p \in \Sigma\}$. For $\alpha \in \mathcal{L}_\Sigma$, we define $\alpha^\pm$ as the formula obtained from α by replacing each negative occurrence of p by $\neg p^-$ and by replacing each positive occurrence of p by p^+ , for each propositional variable p in Σ . For example $(p \wedge (p \rightarrow q))^\pm = p^+ \wedge (\neg p^- \rightarrow q^+)$. This is defined analogously for sets of formulas. Observe that for any set $T \subseteq \mathcal{L}_\Sigma$, $T^\pm$ is consistent, even if T is inconsistent.

2.2 Quantified Boolean Formulas

Quantified Boolean formulas (QBFs) generalise ordinary propositional formulas by the admission of quantifications over propositional variables (QBFs are denoted by Greek upper-case letters). Informally, a QBF of form $\forall p \exists q \Phi$ means that for all truth assignments of p there is a truth assignment of q such that Φ is true. For instance, it is easily seen that the QBF $\exists p \exists q ((p \rightarrow q) \wedge \forall r (r \rightarrow q))$ evaluates to true.

The precise semantical meaning of QBFs is defined as follows. First, some ancillary notation. An occurrence of a propositional variable p in a QBF Φ is *free* iff it does not appear in the scope of a quantifier Qp ($Q \in \{\forall, \exists\}$), otherwise the occurrence of p is *bound*. If Φ contains no free variable occurrences, then Φ is *closed*, otherwise Φ is *open*. Furthermore, we write $\Phi[p_1/\phi_1, \dots, p_n/\phi_n]$ to denote the result of uniformly substituting each free occurrence of a variable p_i in Φ by a formula ϕ_i , for $1 \leq i \leq n$.

By an *interpretation*, M , we understand a set of atoms. Informally, an atom p is true under M iff $p \in M$. In general, the truth value, $\nu_M(\Phi)$, of a QBF Φ under an interpretation M is recursively defined as follows:

1. if $\Phi = \top$, then $\nu_M(\Phi) = 1$;
2. if $\Phi = p$ is an atom, then $\nu_M(\Phi) = 1$ if $p \in M$, and $\nu_M(\Phi) = 0$ otherwise;
3. if $\Phi = \neg\Psi$, then $\nu_M(\Phi) = 1 - \nu_M(\Psi)$;
4. if $\Phi = (\Phi_1 \wedge \Phi_2)$, then $\nu_M(\Phi) = \min(\{\nu_M(\Phi_1), \nu_M(\Phi_2)\})$;
5. if $\Phi = \forall p \Psi$, then $\nu_M(\Phi) = \nu_M(\Psi[p/\top] \wedge \Psi[p/\perp])$;
6. if $\Phi = \exists p \Psi$, then $\nu_M(\Phi) = \nu_M(\Psi[p/\top] \vee \Psi[p/\perp])$.

The truth conditions for $\perp$, $\vee$, $\rightarrow$, and $\equiv$ follow from the above in the usual way. We say that Φ is *true under* M iff $\nu_M(\Phi) = 1$, otherwise Φ is *false under* M . If $\nu_M(\Phi) = 1$, then M is a *model* of Φ . If Φ has some model, then Φ is said to be

satisfiable. If Φ is true under any interpretation, then Φ is *valid*. As usual, we write $\models \Phi$ to express that Φ is valid. Observe that a closed QBF is either valid or unsatisfiable, because closed QBFs are either true under each interpretation or false under each interpretation. Hence, for closed QBFs, there is no need to refer to particular interpretations. Two sets of QBFs (or ordinary formulas) are *logically equivalent* iff they possess the same models.

In the sequel, we use the following abbreviations in the context of QBFs: For a set $P = \{p_1, \dots, p_n\}$ of propositional variables and a quantifier $Q \in \{\forall, \exists\}$, we let $QP\Phi$ stand for the formula $Qp_1Qp_2 \dots Qp_n\Phi$. Furthermore, for indexed sets $S = \{\phi_1, \dots, \phi_n\}$ and $T = \{\psi_1, \dots, \psi_n\}$ of formulas, $S \leq T$ abbreviates $\bigwedge_{i=1}^n (\phi_i \rightarrow \psi_i)$.

The operator $\leq$ is a fundamental tool for expressing certain tests on sets of formulas in terms of QBFs. In particular, we use $\leq$ for expressing the following task:

Given finite sets S and T of formulas, compute all subsets $R \subseteq S$ such that $T \cup R$ is consistent.

This problem can be encoded by a QBF in the following way:

Proposition 1. *Let $S = \{\phi_1, \dots, \phi_n\}$ and T be finite sets of formulas, let $P = \text{var}(S \cup T)$, and let $G = \{g_1, \dots, g_n\}$ be a set of new variables. Furthermore, for any $S' \subseteq S$, define the interpretation $M_{S'} \subseteq G$ such that $\phi_i \in S'$ iff $g_i \in M_{S'}$, for $1 \leq i \leq n$.*

Then, $T \cup S'$ is consistent iff the QBF

$$\mathcal{C}[T, S] = \exists P(T \wedge (G \leq S))$$

is true under $M_{S'}$.

Theorem 1. *Given the prerequisites of Proposition 1, we have that S' is a maximal subset of S consistent with T iff $M_{S'}$ is a model of the QBF*

$$\mathcal{C}[T, S] \wedge \bigwedge_{i=1}^n \left(\neg g_i \rightarrow \neg \mathcal{C}[T \cup \{\phi_i\}, S \setminus \{\phi_i\}] \right).$$

2.3 Default Logic

The primary technical means for dealing with “signed theories” is *default logic* [18], whose central concepts are *default rules* along with their induced *extensions* of an initial set of premises. A default rule (or *default* for short)

$$\frac{\alpha : \beta}{\gamma}$$

has two types of antecedents: a *prerequisite* α which is established if α is derivable and a *justification* β which is established if β is consistent. If both conditions

hold, the *consequent* γ is concluded by default. For convenience, we denote the prerequisite of a default δ by $p(\delta)$, its justification by $j(\delta)$, and its consequent by $c(\delta)$. Accordingly, for a set of defaults D , we define $p(D) = \{p(\delta) \mid \delta \in D\}$, $j(D) = \{j(\delta) \mid \delta \in D\}$, and $c(D) = \{c(\delta) \mid \delta \in D\}$.

A *default theory* is a pair (D, W) where D is a set of default rules and W a set of formulas. A set of conclusions (sanctioned by a given set of default rules and by means of classical logic) is called an *extension* of an initial set of facts. More formally, extensions are defined as follows:

Definition 1 ([18]). Let (D, W) be a default theory and let E be a set of formulas. Define $E_1 = W$ and, for $n \geq 1$,

$$E_{n+1} = Cn(E_n) \cup \left\{ \gamma \mid \frac{\alpha : \beta}{\gamma} \in D, \alpha \in E_n, \neg\beta \notin E \right\}.$$

Then, E is an extension of (D, W) iff $E = \bigcup_{n \in \omega} E_n$.

3 Signed Systems

The basic idea of signed systems is to transform an inconsistent theory into a consistent one by renaming propositional variables and then to extend the resulting signed theory by equivalences using default logic.

3.1 Basic Approach

Starting with a possibly inconsistent finite theory $W \subseteq \mathcal{L}_\Sigma$, we consider the default theory obtained from $W^\pm$ and a set of default rules $D_\Sigma = \{\delta_p \mid p \in \Sigma\}$ defined in the following way. For each propositional letter p in Σ , we define

$$\delta_p = \frac{p^+ \equiv \neg p^-}{(p \equiv p^+) \wedge (\neg p \equiv p^-)} . \quad (1)$$

Using this definition, we define the first family of paraconsistent consequence relations:

Definition 2. Let W be a finite set of formulas in $\mathcal{L}_\Sigma$ and let φ be a formula in $\mathcal{L}_\Sigma$. Let $\mathcal{E}$ be the set of all extensions of $(D_\Sigma, W^\pm)$. For each set of formulas $S \subseteq \mathcal{L}_{\Sigma \cup \Sigma^\pm}$, let

$$\Pi_S = \{c(\delta_p) \mid p \in \Sigma, \neg j(\delta_p) \notin S\}.$$

Then, we define

$$\begin{array}{ll} W \vdash_c \varphi & \text{iff } \varphi \in \bigcup_{E \in \mathcal{E}} Cn(W^\pm \cup \Pi_E) \quad (\text{credulous unsigned}^1 \text{ consequence}) \\ W \vdash_s \varphi & \text{iff } \varphi \in \bigcap_{E \in \mathcal{E}} Cn(W^\pm \cup \Pi_E) \quad (\text{skeptical unsigned consequence}) \\ W \vdash_p \varphi & \text{iff } \varphi \in Cn(W^\pm \cup \bigcap_{E \in \mathcal{E}} \Pi_E) \quad (\text{prudent unsigned consequence}) \end{array}$$

¹ The term “unsigned” indicates that only unsigned formulas are taken into account.

For illustration, consider the inconsistent theory

$$W = \{p, q, \neg p \vee \neg q\}. \quad (2)$$

For obtaining the above paraconsistent consequence relations, W is turned into the default theory²

$$(D_\Sigma, W^\pm) = (\{\delta_p, \delta_q\}, \{p^+, q^+, p^- \vee q^-\}).$$

We obtain two extensions, viz. $Cn(W^\pm \cup \{c(\delta_p)\})$ and $Cn(W^\pm \cup \{c(\delta_q)\})$. The following relations show how the different consequence relations behave:

$$W \vdash_c p, \quad W \not\vdash_s p, \quad W \not\vdash_p p,$$

but, for instance,

$$W \vdash_c p \vee q, \quad W \vdash_s p \vee q, \quad W \not\vdash_p p \vee q.$$

For a complement, the following “signed” counterparts are defined.

Definition 3. *Given the prerequisites of Definition 2, we define*

$$\begin{aligned} W \vdash^\pm \varphi & \text{ iff } \varphi^\pm \in \bigcup_{E \in \mathcal{E}} Cn(W^\pm \cup \Pi_E) & (\text{credulous signed consequence}) \\ W \vdash_s^\pm \varphi & \text{ iff } \varphi^\pm \in \bigcap_{E \in \mathcal{E}} Cn(W^\pm \cup \Pi_E) & (\text{skeptical signed consequence}) \\ W \vdash_p^\pm \varphi & \text{ iff } \varphi^\pm \in Cn(W^\pm \cup \bigcap_{E \in \mathcal{E}} \Pi_E) & (\text{prudent signed consequence}) \end{aligned}$$

3.2 Formal Properties

As shown in [2], these relations compare to each other in the following way.

Theorem 2. *Let C_i be the operator corresponding to $C_i(W) = \{\varphi \mid W \vdash_i \varphi\}$ where i ranges over $\{p, s, c\}$, and similarly for $C_i^\pm$. Then, we have*

1. $C_i(W) \subseteq C_i^\pm(W)$;
2. $C_p(W) \subseteq C_s(W) \subseteq C_c(W)$ and $C_p^\pm(W) \subseteq C_s^\pm(W) \subseteq C_c^\pm(W)$.

That is, signed derivability gives more conclusions than unsigned derivability and within each series of consequence relations the strength of the relation is increasing.

Moreover, they enjoy the following logical properties:

Theorem 3. *Let C_i be the operator corresponding to $C_i(W) = \{\varphi \mid W \vdash_i \varphi\}$ where i ranges over $\{p, s, c\}$, and similarly for $C_i^\pm$. Then, we have*

3. $W \subseteq C_i^\pm(W)$;
4. $C_p(W) = Cn(C_p(W))$ and $C_s(W) = Cn(C_s(W))$;
5. $C_i^\pm(W) = C_i^\pm(C_i^\pm(W))$;
6. $Cn(W) \neq \mathcal{L}_\Sigma$ only if $Cn(W) = C_i(W) = C_i^\pm(W)$;
7. $C_i(W) \neq \mathcal{L}_\Sigma$ and $C_i^\pm(W) \neq \mathcal{L}_\Sigma$;
8. $W \subseteq W'$ does not imply $C_i(W) \subseteq C_i(W')$, and $W \subseteq W'$ does not imply $C_i^\pm(W) \subseteq C_i^\pm(W')$.

The last item simply says that all of our consequence relations are nonmonotonic. For instance, we have $C_i(\{A, A \rightarrow B\}) = C_i^\pm(\{A, A \rightarrow B\}) = Cn(\{A, B\})$, while neither $C_i(\{A, \neg A, A \rightarrow B\})$ nor $C_i^\pm(\{A, \neg A, A \rightarrow B\})$ contains B .

² For simplicity, we omitted all δ_x for $x \in \Sigma \setminus \{p, q\}$.

3.3 Refinements

The previous relations embody a somewhat global approach in restoring semantic links between positive and negative literals. In fact, the application of a rule δ_p re-establishes the semantic link between all occurrences of proposition p and its negation $\neg p$ at once. A more fine-grained approach is to establish the connections between complementary occurrences of an atom individually.

Formally, for a given W and an index set I assigning different indices to all occurrences of all atoms in W , define

$$\delta_p^{i,j} = \frac{:(p \equiv p_i^+) \wedge (\neg p \equiv p_j^-)}{(p \equiv p_i^+) \wedge (\neg p \equiv p_j^-)} \quad (3)$$

for all $p \in \Sigma$ and all $i, j \in I$, provided that i and j refer to complementary occurrences of p in W , otherwise set $\delta_p^{i,j} = \delta_p$. Denote by D_Σ^1 this set of defaults and by $W_I^\pm$ the result of replacing each $p^+ \in W^\pm$ (resp., $p^- \in W^\pm$) by p_i^+ (resp., p_i^-) where i is the index assigned to the corresponding occurrence, provided that there are complementary occurrences of p in W .

Finally, abandoning the restoration of semantical links and foremost restoring original (unsigned) literals leads to the most adventurous approach to signed inferences. Consider the following set of defaults, defined for all $p \in \Sigma$ and $i, j \in I$,

$$\delta_p^{i+} = \frac{:(p \equiv p_i^+)}{(p \equiv p_i^+)} \quad \delta_p^{j-} = \frac{:(\neg p \equiv p_j^-)}{(\neg p \equiv p_j^-)} \quad (4)$$

for all positive and negative occurrences of p , respectively. As above, we use these defaults provided that there are complementary occurrences of p in W , otherwise use δ_p . A set of defaults of form (4) with respect to W is denoted by D_Σ^2 .

Thus, further consequence relations are defined when $(D_\Sigma, W^\pm)$ in Definition 2 is replaced by $(D_\Sigma^1, W_I^\pm)$ or by $(D_\Sigma^2, W_I^\pm)$. Similar results to Theorem 2 and 3 can be shown for these families of consequence relations.

In the following, we identify all introduced default theories as follows. Given a finite set $W \subseteq \mathcal{L}_\Sigma$, the class $\mathcal{D}(W)$ contains (D_Σ, W) , as well as $(D_\Sigma^1, W_I^\pm)$ and $(D_\Sigma^2, W_I^\pm)$ for any index set I . Furthermore, $\mathcal{D} = \bigcup_{W \subseteq \mathcal{L}_\Sigma} \mathcal{D}(W)$ denotes the class of all possible default theories under consideration.

3.4 Hierarchic Extensions

Whenever a problem instance may give rise to several solutions, it is useful to provide a preference criterion for selecting a subset of preferred solutions. This is accomplished in [2] by means of a *ranking function* $\varrho : \Sigma \rightarrow \mathbb{N}$ on the alphabet Σ for inducing a hierarchy on the default rules in D_Σ :

Definition 4. Let $\varrho : \Sigma \rightarrow \mathbb{N}$ be some ranking function on alphabet Σ , and $(D, V) \in \mathcal{D}$. We define the hierarchy of D with respect to ϱ as the partition

$\langle D_n \rangle_{n \in \omega}$ of D such that for each $\delta \in D$ with δ of form $\delta_p, \delta_p^{i,j}, \delta_p^{i+}, \delta_p^{i-}$, for $p \in \Sigma$ and $i, j \in I$, $\delta \in D_n$ iff $\varrho(p) = n$ holds.

Strictly speaking, $\langle D_n \rangle_{n \in \omega}$ is not always a genuine partition, since D_n may be the empty set for some values of n .

Such rankings are used for inducing so-called *hierarchic extensions*. This concept has been introduced to deal with a given partition on the defaults D of a default theory (D, V) .

Definition 5. Let W be a finite set of formulas in $\mathcal{L}_\Sigma$, $(D, V) \in \mathcal{D}(W)$, and E a set of formulas. Let $\langle D_n \rangle_{n \in \omega}$ be the hierarchy of D with respect to some ranking function ϱ .

Then, $E = \bigcup_{n \in \omega} E_n$ is a hierarchic extension of (D, V) relative to ϱ if $E_1 = V$ and E_{n+1} is an extension of (D_n, E_n) for all $n \geq 1$.

Let $\langle D_n \rangle_{n \in \omega}$ be the hierarchy of D with respect to some ranking function ϱ , and let $\mathcal{E}$ be the set of all hierarchic extensions of a default theory $(D, V) \in \mathcal{D}$ in Definition 2. Then, we immediately get corresponding consequence relations $\vdash_{ch}$, $\vdash_{sh}$, and $\vdash_{ph}$. Furthermore, applying hierarchic extensions on default theories $(D_\Sigma, W^\pm)$ in accordance to Definition 3 yields new relations $\vdash_{ch}^\pm$, $\vdash_{sh}^\pm$, and $\vdash_{ph}^\pm$.

In concluding this section, let us briefly recapitulate all paraconsistent consequence relations introduced so far. As a basic classification, we have credulous, skeptical and prudent consequence. For each of these relations, we defined unsigned operators, which are invocable on three different classes of default theories (viz. on $(D_\Sigma, W^\pm)$, $(D_\Sigma^1, W_I^\pm)$, and $(D_\Sigma^2, W_I^\pm)$), either on ordinary extensions ($\vdash_i$) or on hierarchic extensions ($\vdash_{ih}$), and, on the other hand, signed operators also relying on ordinary extensions ($\vdash_i^\pm$) or hierarchic extensions ($\vdash_{ih}^\pm$) of the default theory $(D_\Sigma, W^\pm)$. This gives in total 18 unsigned and 6 signed paraconsistent consequence relations, which shall all be considered in the following two sections.

4 Reductions

In this section, we show how the above introduced consequence relations can be mapped into quantified Boolean formulas in polynomial time.

Recall the set $\mathcal{D}(W)$ for finite $W \subseteq \mathcal{L}_\Sigma$. In what follows, we use finite default theories

$$\mathcal{D}^*(W) = \{(D_W, V) \mid (D, V) \in \mathcal{D}(W)\}$$

where $D_W = \{\delta \in D \mid \text{var}(\delta) \cap \text{var}(W) \neq \emptyset\}$. Hence, D_W contains each default from D having an unsigned atom which also occurs in W .

The next subsection shows the adequacy of these default theories. Afterwards, Section 4.2 gives QBF-reductions based on the finite default theories $\mathcal{D}^*(W)$.

4.1 Finitary Characterisations

Lemma 1. *Let $W \subseteq \mathcal{L}_\Sigma$ be a finite set of formulas and $(D, V) \in \mathcal{D}(W)$ a default theory. Moreover, let $C \subseteq D$ and $C_W = \{\delta \in C \mid \text{var}(\delta) \cap \text{var}(W) \neq \emptyset\}$. Then,*

1. $Cn(V \cup c(C_W)) \cap \mathcal{L}_\Sigma = Cn(V \cup c(C)) \cap \mathcal{L}_\Sigma$; and
2. for each $\varphi^\pm \in \mathcal{L}_{\Sigma^\pm}$, $\varphi^\pm \in Cn(V \cup c(C))$ iff $\varphi^\pm \in Cn(V \cup c(C_W) \cup c(D_\varphi))$ where $D_\varphi = \{\delta_p \mid p \in \text{var}(\varphi) \setminus \text{var}(W)\}$.

Both results show that having computed a (possibly hierarchic) extension, one has a finite set of generating defaults sufficient for deciding whether a para-consistent consequence relation holds. The following result shows that these sets are also sufficient to compute the underlying extensions themselves.

Theorem 4. *Let W , (D, V) , C , and C_W be as in Lemma 1, and let $D_W = \{\delta \in D \mid \text{var}(\delta) \cap \text{var}(W) \neq \emptyset\}$.*

Then, there is a one-to-one correspondence between the extensions of (D, V) and the extensions of (D_W, V) . In particular, $Cn(V \cup c(C))$ is an extension of (D, V) iff $Cn(V \cup c(C_W))$ is an extension of (D_W, V) . Similar relations hold for hierarchic extensions as well.

The next result gives a uniform characterisation for all default theories under consideration. It follows from the fact that, for each δ_p , the consequent $(p \equiv p^+) \wedge (\neg p \equiv p^-)$ is actually equivalent to $(p^+ \equiv \neg p^-) \wedge (p \equiv p^+)$, and, furthermore, that defaults of form (3) and (4) share the property that their justifications and consequents are identical. Hence, given W and I as usual, it holds that $c(\delta) \models j(\delta)$, for each $\delta \in D$, with $(D, V) \in \mathcal{D}^*(W)$.

Theorem 5. *Let $W \subseteq \mathcal{L}_\Sigma$ be a finite set of formulas, let $(D, V) \in \mathcal{D}^*(W)$ be a default theory, and let $C \subseteq D$.*

Then, $Cn(V \cup c(C))$ is an extension of (D, V) iff $j(C)$ is a maximal subset of $j(D)$ consistent with V .

Note that the subsequent QBF reductions, obtained on the basis of the above result, represent a more compact axiomatics than the encodings given in [8] for arbitrary default theories.

We derive an analogous characterisation for hierarchic extensions. In fact, each hierarchic extension is also an extension (but not vice versa) [2]. Thus, we can characterise hierarchic extensions of a default theory (D, V) as ordinary extensions, viz. by $Cn(W \cup c(C))$ with $C \subseteq D$ suitably chosen. The following result generalises Theorem 5 with respect to a given partition on the defaults. In particular, if $\langle D_n \rangle_{n \in \omega} = \langle D \rangle$, Theorem 6 corresponds to Theorem 5.

Theorem 6. *Let W , (D, V) , and C be given as in Theorem 5.*

Then, $Cn(V \cup c(C))$ is a hierarchic extension of (D, V) with respect to partition $\langle D_n \rangle_{n \in \omega}$ on D iff for each $i \in \omega$, $j(D_i \cap C)$ is a maximal subset of $j(D_i)$ consistent with $V \cup \bigcup_{j < i} c(D_j \cap C)$.

Finally, in order to relate extensions of default theories to paraconsistent consequence operators, we note the following straightforward observations.

Let Π_S be as in Definition 2. Then, for each extension E of $(D, V) \in \mathcal{D}(W)$, there exists a $C \subseteq D$ such that $c(C) = \Pi_E$. However, since we have to check whether a given formula is contained in some $Cn(V \cup \Pi_E)$, by Lemma 1 it is obviously sufficient to consider just the generating defaults of an extension of the corresponding restricted default theory from $\mathcal{D}^*(W)$. In view of Theorems 5 and 6, this immediately implies that all paraconsistent consequence relations introduced so far can be characterised by maximal subsets of the consequences $c(D)$ of the corresponding default theory $(D, V) \in \mathcal{D}^*(W)$. More specifically, credulous and skeptical paraconsistent consequence reduces to checking whether a given formula is contained in at least one or respectively all such maximal subsets. Additionally, prudent consequence enjoys the following property.

Lemma 2. *Let $W \subseteq \mathcal{L}_\Sigma$ be a finite set of formulas, and $(D, V) \in \mathcal{D}^*(W)$.*

Then, for each $\varphi \in \mathcal{L}_\Sigma$, we have that $W \not\vdash_p \varphi$ (resp., $W \not\vdash_{ph} \varphi$) iff there exists a set $C \subseteq D$ such that $\varphi \notin Cn(V \cup c(C))$ and, for each $\delta \in D \setminus C$, there is some extension (resp., hierarchic extension) E of (D, V) such that $c(\delta) \notin E$. An analogous result holds for relations $\vdash_p^\pm$ and $\vdash_{ph}^\pm$.

4.2 Main Construction

We start with some basic QBF-modules. To this end, recall the schema $\mathcal{C}[\cdot, \cdot]$ from Proposition 1.

Definition 6. *Let $W \subseteq \mathcal{L}_\Sigma$ be a finite set of formulas and $\varphi \in \mathcal{L}_\Sigma$. For each finite default theory $T = (D, V) \in \mathcal{D}^*(W)$, let $D = \{\delta_1, \dots, \delta_n\}$, and define*

$$\begin{aligned} \mathcal{E}xt[T] &= \mathcal{C}[V, j(D)] \wedge \bigwedge_{i=1}^n \left(\neg g_i \rightarrow \neg \mathcal{C}[V \cup \{j(\delta_i)\}, j(D \setminus \{\delta_i\})] \right); \\ \mathcal{C}onseq[T, \varphi] &= \forall P \left(V \wedge (G \leq c(D)) \rightarrow \varphi \right), \end{aligned}$$

where P denotes the set of atoms occurring in T or φ , and $G = \{g_i \mid \delta_i \in D\}$ is an indexed set of globally new variables corresponding to D .

Lemma 3. *Let W , $T = (D, V)$, and G be as in Definition 6. Furthermore, for any set $C \subseteq D$, define the interpretation $M_C \subseteq G$ such that $g_i \in M_C$ iff $\delta_i \in C$, for $1 \leq i \leq n$.*

Then, the following relations hold:

1. $Cn(V \cup c(C))$ is an extension of T iff $\mathcal{E}xt[T]$ is true under M_C ; and
2. $\varphi \in Cn(V \cup c(C))$ iff $\mathcal{C}onseq[T, \varphi]$ is true under M_C , for any formula φ in $\mathcal{L}_\Sigma$.

Observe that the correctness of Condition 1 follows directly from Theorem 1, since we have that $\mathcal{Ext}[T]$ is true under M_C iff $j(C)$ is a maximal subset of $j(D)$ consistent with V , and, in view of Theorem 5, the latter holds iff $Cn(V \cup c(C))$ is an extension of T . Moreover, Condition 2 is actually reducible to Proposition 1. Combining these two QBF-modules, we obtain encodings for the basic inference tasks as follows:

Theorem 7. *Let $W \subseteq \mathcal{L}_\Sigma$ be a finite set of formulas, $T = (D, V)$ a default theory from $\mathcal{D}^*(W)$ with $D = \{\delta_1, \dots, \delta_n\}$, φ a formula in $\mathcal{L}_\Sigma$, and $G = \{g_1, \dots, g_n\}$ the indexed set of variables occurring in $\mathcal{Ext}[T]$ and $\text{Conseq}[T, \varphi]$.*

Then, paraconsistent credulous and skeptical consequence relations can be axiomatised by means of QBFs as follows:

1. $W \vdash_c \varphi$ iff $\models \exists G(\mathcal{Ext}[T] \wedge \text{Conseq}[T, \varphi])$; and
2. $W \vdash_s \varphi$ iff $\models \neg \exists G(\mathcal{Ext}[T] \wedge \neg \text{Conseq}[T, \varphi])$.

Moreover, for prudent consequence, let $G' = \{g'_i \mid g_i \in G\}$ be an additional set of globally new variables and

$$\Psi = \bigwedge_{i=1}^n \left(\neg g'_i \rightarrow \exists G(\mathcal{Ext}[T] \wedge \neg \text{Conseq}[T, c(\delta_i)]) \right).$$

Then,

3. $W \vdash_p \varphi$ iff $\models \neg \exists G'(\neg \text{Conseq}_{G \leftarrow G'}[T, \varphi] \wedge \Psi)$,

where $\text{Conseq}_{G \leftarrow G'}[T, \varphi]$ denotes the QBF obtained from $\text{Conseq}[T, \varphi]$ by replacing each occurrence of an atom $g \in G$ in $\text{Conseq}[T, \varphi]$ by g' .

In what follows, we discuss the remaining consequence relations under consideration. We start with signed consequence. Here, we just have to adopt the calls to $\text{Conseq}[(D_\Sigma, W^\pm), \varphi]$ with respect to Lemma 2, by adding those defaults δ_p to $W^\pm$ such that $p \in \text{var}(\varphi) \setminus \text{var}(W)$. Observe that in the following theorem this addition is *not* necessary for the module Ψ . Furthermore, recall that signed consequence is applied only to default theories $(D_\Sigma, W^\pm)$.

Theorem 8. *Let $W \subseteq \mathcal{L}_\Sigma$ be a finite set of formulas and φ a formula in $\mathcal{L}_\Sigma$. Moreover, let $D_W = \{\delta_p \mid p \in \text{var}(W)\}$ and $D_\varphi = \{\delta_p \mid p \in \text{var}(\varphi) \setminus \text{var}(W)\}$, with the corresponding default theories $T = (D_W, W^\pm)$ and $T' = (D_W, W^\pm \cup c(D_\varphi))$, and let G, G' , and Ψ be as in Theorem 7.*

Then, paraconsistent signed consequence relations can be axiomatised by means of QBFs as follows:

1. $W \vdash_c^\pm \varphi$ iff $\models \exists G(\mathcal{Ext}[T] \wedge \text{Conseq}[T', \varphi^\pm])$;
2. $W \vdash_s^\pm \varphi$ iff $\models \neg \exists G(\mathcal{Ext}[T] \wedge \neg \text{Conseq}[T', \varphi^\pm])$; and
3. $W \vdash_p^\pm \varphi$ iff $\models \neg \exists G'(\Psi \wedge \neg \text{Conseq}_{G \leftarrow G'}[T', \varphi^\pm])$,

where, as above, $\text{Conseq}_{G \leftarrow G'}[\cdot, \cdot]$ replaces each g by g' .

It remains to consider the consequence relations based on hierarchical extensions. To this end, we exploit the characterisation of Theorem 6.

Definition 7. Let $W \subseteq \mathcal{L}_\Sigma$ be a finite set of formulas, $T = (D, V)$ a default theory from $\mathcal{D}^*(W)$ with $D = \{\delta_1, \dots, \delta_n\}$, and $P = \langle D_n \rangle_{n \in \omega}$ a partition on D . We define

$$\mathcal{Ext}_h[T, P] = \bigwedge_{i \in \omega} \left(\mathcal{Ext}[(V \wedge \bigwedge_{\delta_j \in D_1 \cup \dots \cup D_{i-1}} (g_j \rightarrow c(\delta_j)), D_i] \right),$$

where $G = \{g_i \mid \delta_i \in D\}$ is the same indexed set of globally new variables corresponding to D as above appearing in each $\mathcal{Ext}[\cdot]$.

Lemma 4. Let W , (D, V) , G , and P be as in Definition 7. Furthermore, for any set $C \subseteq D$, define the interpretation $M_C \subseteq G$ such that $g_i \in M_C$ iff $\delta_i \in C$, for $1 \leq i \leq n$.

Then, $Cn(V \cup c(C))$ is a hierarchic extension of T with respect to P iff $\mathcal{Ext}_h[T, P]$ is true under M_C .

Theorem 9. Paraconsistent consequence relations $\vdash_{ch}$, $\vdash_{ch}^\pm$, $\vdash_{sh}$, $\vdash_{sh}^\pm$, $\vdash_{ph}$, and $\vdash_{ph}^\pm$ are expressible in the same manner as in Theorems 7 and 8 by replacing $\mathcal{Ext}[T]$ with $\mathcal{Ext}_h[T, P]$.

This concludes the reductions to QBFs. Observe that all these reductions are solely built from simple QBF-modules like $\mathcal{Ext}[\cdot]$ and $Conseq[\cdot, \cdot]$ and are constructible in polynomial time.

5 Complexity Issues

In what follows, we assume the reader familiar with the basic concepts of complexity theory (cf. e.g., [16] for a comprehensive textbook on this subject). Relevant for our purposes are the complexity classes Σ_2^P and Π_2^P . Σ_2^P is the class of all problems solvable on a nondeterministic Turing machine in polynomial time having access to an oracle for problems in NP (the class NP consists of all decision problems which can be solved with a nondeterministic Turing machine working in polynomial time), and Π_2^P consists of the problems which are complementary to the problems in Σ_2^P , i.e., $\Pi_2^P = \text{co-}\Sigma_2^P$. Recall that both classes are part of the polynomial hierarchy.

In the sequel, we derive complexity results for deciding paraconsistent consequence in all variants discussed previously. We show that all considered tasks are located at the second level of the polynomial hierarchy. This is in some sense not surprising, because the current approach relies on deciding whether a given formula is contained in an extension of a suitably constructed default theory. This problem was shown to be Σ_2^P -complete by Gottlob [13], even if normal default theories are considered. However, this completeness result is not directly

applicable here because of the specialised default theories in the present setting. Furthermore, for dealing with hierarchic extensions, it turns out that the complexity remains at the second level of the polynomial hierarchy as well. This result is interesting, since the definition of hierarchic extensions is somewhat more elaborate than standard extensions. In any case, this observation mirrors in some sense complexity results derived for cumulative default logic (cf. [14]).

In the same way as the satisfiability problem of classical propositional logic is the “prototypical” problem of NP, i.e., being an NP-complete problem, the satisfiability problem of QBFs in *prenex form* possessing k quantifier alternations is the “prototypical” problem of the k -th level of the polynomial hierarchy.

Proposition 2 ([19]). *Given a propositional formula ϕ whose atoms are partitioned into $i \geq 1$ sets $P_1, \dots, P_i$, deciding whether $\exists P_1 \forall P_2 \dots Q_i P_i \phi$ is true is Σ_i^P -complete, where $Q_i = \exists$ if i is odd and $Q_i = \forall$ if i is even. Dually, deciding whether $\forall P_1 \exists P_2 \dots Q'_i P_i \phi$ is true is Π_i^P -complete, where $Q'_i = \forall$ if i is odd and $Q'_i = \exists$ if i is even.*

Given the above characterisations, we can estimate upper complexity bounds for the reasoning problems discussed in Section 3 simply by inspecting the quantifier order of the respective QBF encodings. This can be argued as follows. First of all, by applying quantifier transformation rules similar to ones in first-order logic, each of the above QBF encodings can be transformed in polynomial time into a QBF in prenex form having exactly one quantifier alternation. Then, by invoking Proposition 2 and observing that completeness of a decision problem D for a complexity class C implies membership of D in C , the quantifier order of the resultant QBFs determines in which class of the polynomial hierarchy the corresponding reasoning task belongs to.

Applying this method to our considered tasks, we obtain that credulous paraconsistent reasoning lies in Σ_2^P , whilst skeptical and prudent paraconsistent reasoning are in Π_2^P . Furthermore, note that the QBFs expressing paraconsistent reasoning using the concept of hierarchical extensions share exactly the same quantifier structures as those using ordinary extensions.

Concerning lower complexity bounds, it turns out that most of the above given estimations are *strict*, i.e., the considered decision problems are hard for the respective complexity classes. The results are summarised in Table 1. There, all entries denote completeness results, except where a membership relation is explicitly stated. The following theorem summarises these relations:

Theorem 10. *The complexity results in Table 1 hold both for ordinary as well as for hierarchical extensions of T_i ($i = 0, 1, 2$) as underlying inference principle.*

Some of these complexity results have already been shown elsewhere. As pointed out in [2], prudent consequence, $W \vdash_p \varphi$, on the basis of the default theory $(D_\Sigma, W^\pm)$ captures the notion of *free-consequences* as introduced in [1]. This formalism was shown to be Π_2^P -complete in [4].

Finally, [5] considers the complexity of a number of different paraconsistent reasoning principles, among them the completeness results for $\vdash_s$ and $\vdash_s^\pm$. More-

Table 1. Complexity results for all paraconsistent consequence relations.

	$T_0 = (D_\Sigma, W^\pm)$	$T_1 = (D_\Sigma^1, W_I^\pm)$	$T_2 = (D_\Sigma^2, W_I^\pm)$
$\vdash_c$	Σ_2^P	Σ_2^P	Σ_2^P
$\vdash_s$	Π_2^P	Π_2^P	Π_2^P
$\vdash_p$	Π_2^P	in Π_2^P	in Π_2^P
$\vdash_c^\pm$	Σ_2^P	-	-
$\vdash_s^\pm$	Π_2^P	-	-
$\vdash_p^\pm$	in Π_2^P	-	-
$\vdash_{ch}$	Σ_2^P	Σ_2^P	Σ_2^P
$\vdash_{sh}$	Π_2^P	Π_2^P	Π_2^P
$\vdash_{ph}$	Π_2^P	in Π_2^P	in Π_2^P
$\vdash_{ch}^\pm$	Σ_2^P	-	-
$\vdash_{sh}^\pm$	Π_2^P	-	-
$\vdash_{ph}^\pm$	in Π_2^P	-	-

over, that paper extends the intractability results to some restricted subclasses as well.

6 Discussion

We have shown how paraconsistent inference problems within the framework of signed systems can be axiomatised by means of quantified Boolean formulas. This approach has several benefits: First, the given axiomatics provides us with further insight about how paraconsistent reasoning works within the framework of signed systems. Second, this axiomatisation allows us to furnish upper bounds for precise complexity results, going beyond those presented in [5]. Last but not least, we obtain a straightforward implementation technique of paraconsistent reasoning in signed systems by appeal to existing QBF solvers.

For implementing our approach, we rely on the existing system QUIP [8,7]. The general architecture of QUIP consists of three parts, namely the **filter** program, a QBF-evaluator, and the interpreter **int**. The input filter translates the given problem description (in our case, a signed system and a specified reasoning task) into the corresponding quantified Boolean formula, which is then sent to the QBF-evaluator. The current version of QUIP provides interfaces to most of the currently available QBF-solvers. The result of the QBF-evaluator is interpreted by **int**. Depending on the capabilities of the employed QBF-evaluator, **int** provides an explanation in terms of the underlying problem instance. This task relies on a protocol mapping of internal variables of the generated QBF into concepts of the problem description.
